Introduction

- Thus far, we have focused on estimation of the phylogenetic tree as the primary goal of our analysis.
- Often, however, the phylogeny itself is not of interest; rather, it is a nusiance parameter.
- One setting in which this occurs is the case where we wish to study relationships among traits, either discrete or continuous, across taxa.
- We'll begin by examining some hypothetical data to motivate the method.

・ロン ・四 ・ ・ ヨン ・ ヨン

Example 1: Correlation between discrete traits

Consider the following traits for 10 taxa:

Stat 882: Statistical Phylogenetics - Lecture 8 - Part I

イロト イヨト イヨト イヨト

Example 1: Correlation between discrete traits

Consider the following traits for 10 taxa:

Fisher's exact test gives a p-value of 0.0048

Example 1: Correlation between discrete traits

▶ But

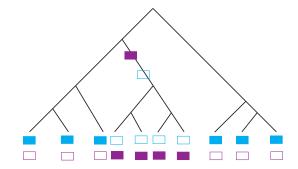

Stat 882: Statistical Phylogenetics - Lecture 8 - Part I

æ

Example 1: Correlation between discrete traits

 Correlation is completely explained by phylogeny: the tree has 18 branches – the probability of two changes on the same branch is then ¹/₁₈ = 0.056.

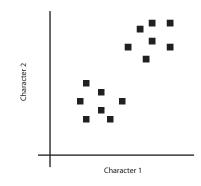

Stat 882: Statistical Phylogenetics - Lecture 8 - Part I

- The problem is that the taxa are not independent outcomes of the evolutionary process; they're all related by the phylogeny.
- We need to model the evolution of traits along the phylogeny and adjust appropriately for correlation due to shared evolutionary history.
- The simplest model of trait evolutionary along a phylogeny is the Brownian motion (BM) model.
- BM was proposed by Robert Brown (1773-1858) based on observation that pollen grains suspended in solutions "jiggled" continually. Later theoretical work is due to Einstein and Weiner, among others.
- BM was first applied to model trait evolution along phylogenies by Edwards and Cavalli-Sforza in 1964.

- Consider a particle moving in a single dimension (say along the x-axis).
- Measure position of particle at small intervals of time.
- ▶ The movement of the particle in each interval is assumed to:
 - be independent of movement in other intervals of time
 - have mean 0
 - have constant variance, regardless of position of the particle
- Consider *n* distinct intervals of time.
- After n steps, the net displacement is the sum of the displacements at each step.

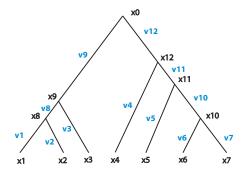

・ロト ・回ト ・ヨト ・ヨト

- ► Let s² be the variance of the displacement at each interval. The variance in the net displacement is then ns² (since the displacement in intervals is independent).
- Now let s² → 0 as n → ∞ such that their product is constant. This is the BM or Weiner process.
- What is important for us is the distribution of the net displacement after t units of time.
- Let σ² be the variance per unit time. Then after t units of time, the variance of the net displacement is σ²t.
- In addition, the net displacement across an interval of t units of time is N(0, σ²t).

BM Along a Phylogeny

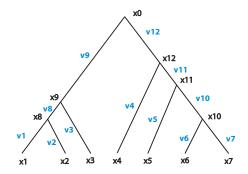

- How do we apply this to trait evolution along a phylogeny?
- Assume that displacements on different branches of a tree are independent; traits evolve over branches of tree according to BM model.

- E

BM Along a Phylogeny: An Example

- Let xi denote the phenotype at node i, and let vi denote the branch length.
- > As an example, look at value of trait at external node 5, x5.

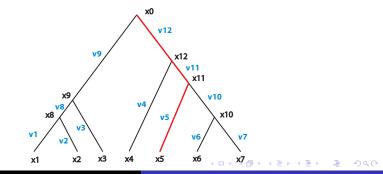

Stat 882: Statistical Phylogenetics - Lecture 8 - Part I

< E

BM Along a Phylogeny: An Example

- Assume that the state at the root (x_0) is fixed.
- ▶ Note that $x_5 = x_0 + (x_{12} x_0) + (x_{11} x_{12}) + (x_5 x_{11})$
- The last three terms above are independent draws from normal distributions with mean 0 and variances depending on the v_i.

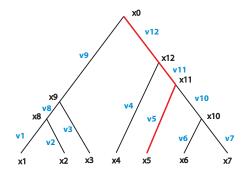

Stat 882: Statistical Phylogenetics - Lecture 8 - Part I

BM Along a Phylogeny: An Example

We have

- $E(x_5) = x_0$
- $Var(x_5) = \sigma^2 v_{12} + \sigma^2 v_{11} + \sigma^2 v_5$

Stat 882: Statistical Phylogenetics - Lecture 8 - Part I

イロト イヨト イヨト イヨト

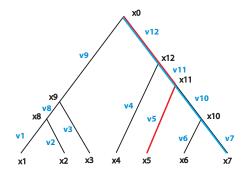

-2

BM Along a Phylogeny: An Example

Similarly, for x_7 , we have

$$\blacktriangleright E(x_7) = x_0$$

• $Var(x_7) = \sigma^2 v_{12} + \sigma^2 v_{11} + \sigma^2 v_{10} + \sigma^2 v_7$

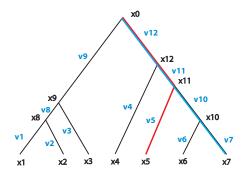

Stat 882: Statistical Phylogenetics - Lecture 8 - Part I

BM Along a Phylogeny: An Example

▶ Note: x_5 and x_7 are not independent – they share a history up to node x_{11}

•
$$cov(x_5, x_7) = \sigma^2 v_{12} + \sigma^2 v_{11}$$

BM Along a Phylogeny

- Now do this for all pairs of tips on a tree.
- The characters on the tips are jointly multivariate normal with expectation x₀ and covariances based on their shared history.
- ► For our example, the variance-covariance matrix is:

 $\begin{pmatrix} \mathsf{v}_1 + \mathsf{v}_3 + \mathsf{v}_9 & \mathsf{v}_3 + \mathsf{v}_9 & \mathsf{v}_9 & 0 & 0 & 0 & 0 \\ \mathsf{v}_8 + \mathsf{v}_9 & \mathsf{v}_2 + \mathsf{v}_8 + \mathsf{v}_9 & \mathsf{v}_9 & 0 & 0 & 0 & 0 \\ \mathsf{v}_9 & \mathsf{v}_9 + \mathsf{v}_8 + \mathsf{v}_9 & \mathsf{v}_9 & 0 & 0 & 0 & 0 \\ 0 & 0 & \mathsf{v}_4 + \mathsf{v}_{12} & \mathsf{v}_{12} & \mathsf{v}_{12} & \mathsf{v}_{12} \\ 0 & 0 & \mathsf{v}_4 + \mathsf{v}_{12} & \mathsf{v}_{12} & \mathsf{v}_{11} + \mathsf{v}_{12} & \mathsf{v}_{12} \\ 0 & 0 & \mathsf{v}_{12} & \mathsf{v}_{11} + \mathsf{v}_{12} & \mathsf{v}_{10} + \mathsf{v}_{11} + \mathsf{v}_{12} & \mathsf{v}_{11} + \mathsf{v}_{12} \\ 0 & 0 & \mathsf{v}_{12} & \mathsf{v}_{11} + \mathsf{v}_{12} & \mathsf{v}_{10} + \mathsf{v}_{11} + \mathsf{v}_{12} & \mathsf{v}_{10} + \mathsf{v}_{11} + \mathsf{v}_{12} \\ 0 & 0 & \mathsf{o} & \mathsf{v}_{12} & \mathsf{v}_{11} + \mathsf{v}_{12} & \mathsf{v}_{10} + \mathsf{v}_{11} + \mathsf{v}_{12} & \mathsf{v}_{10} + \mathsf{v}_{11} + \mathsf{v}_{12} \end{pmatrix} \\ \end{array}$

Inference Under the BM Model

- Suppose that p characters are observed each follows the multivariate normal distribution
- We can write a likelihood function as the product over characters (assuming characters evolve independently along the phylogeny)
- Want to estimate parameters e.g., x_{0i} , $i = 1, \dots p$ and σ_i^2 , $i = 1 \dots p$
- ► However, we run into a problem likelihood goes to ∞ as branch length goes to 0 (see Ch. 23 in text for a worked example).

◆□▶ ◆□▶ ◆目▶ ◆目▶ ◆□ ● ● ●

Inference Under the BM Model

- Some possible solutions:
 - Assume a molecular clock
 - Recode data as differences between character states at the tips – contrasts
- ► Look more at the second case let C be an (n − 1) × n matrix of contrasts.
- Let V be the original variance-covariance matrix (multiplied by σ²).
- Then for the data re-coded as differences in trait values, which we denote by the vector y, we have

$$\mathbf{y} = \mathbf{C}\mathbf{x} \sim \textit{N}(\mathbf{0}, \mathbf{C}\mathbf{V}\mathbf{C}^\mathsf{T})$$

◆□▶ ◆□▶ ◆目▶ ◆目▶ ◆□ ● ● ●

Inference Under the BM Model

- Next, we'll discuss computing the likelihood under this model.
- ► Need a notion of independent contrasts.
